

Data-Driven Product Analysis of 醫健通eHealth App

1. Background

The eHealth App is a Hong Kong government platform for managing personal health records. Despite having over 21,000 ratings on the App Store, recent user feedback suggests a decline in experience. To uncover the real pain points, I developed a Python scraper to extract and analyze recent user reviews.

2. Methodology

I used Apple's official RSS feed to collect 150+ raw reviews from the HK App Store (see `ehealth.py`). After cleaning out noise and irrelevant comments (see `catergorize.py`), I categorized 104 valid reviews into specific pain point categories using keyword-based classification.

3. Key Insights

The data reveals that the app's core issues lie in its foundational user experience:

Pain Point Category	Percentage	Key User Impact
Forced Updates	20%	Users are blocked from using the app until they update, causing significant frustration.
Registration/Login Issues	19%	Many users cannot complete the initial sign-up or log in.
Performance/Crashes	15%	Frequent lagging, freezing, or crashing.
Other Feedback	29%	Miscellaneous feedback (e.g., data sync, minor complaints).
Positive Feedback	5%	Minor positive reviews.
UI/Navigation Issues	3%	Minor interface navigation issues.

User Pain Point Category

According to the data, the largest problems are: Forced updates, registration and performance issue

4. Product Recommendations

Therefore, based on the data analytics, the ehealth could refine its programme by:

Priority	Product Recommendation (Action)	Data Basis (Pain Point)	Business / User Impact
1	Rebuild Onboarding Funnel Integrate "iAM Smart" for online identity verification. Remove mandatory offline registration.	Registration/Login Issues	Fixes the first step of the user journey. Directly reduces user acquisition drop-off and lowers support costs.
2	Upgrade Update Mechanism Replace forced updates with "background download + user-chosen restart". Use soft nudges instead of hard blocks.	Forced Updates	Eliminates hostile interruptions to core tasks. Dramatically improves perceived app stability and user satisfaction.

3	Adopt "Stability First" Roadmap Pause new feature development. Allocate engineering resources exclusively to fixing top crashes and login bugs.	Performance/Crashes	Foundational stability is critical, especially for a government health platform handling sensitive data. Protects user trust.
---	--	---------------------	---

5. Reflection

This analytics project still has areas to improve:

1. **The sample size is too low.** The Analysis is based on 104 valid App Store reviews. Only highly motivated (often frustrated) users leave reviews, creating a negative bias. Next time, I will include more samples into the analysis
2. **Methodological error.** This analysis used only key word matching in data processing. As a result, it frequently mismatches many comments in the wrong field. For example, “好差” in chinese means very bad, but because my key word only include 好 as keyword of positive feedback, this leads to the mismatch. Although I refined the algorithm frequently, the analysis is still not very precise. As improvement, I would use Natural Language Processing (NLP) or manually label more data to improve categorization accuracy and reduce the "Other" bucket.
